

# CCP / Atvise — the numbers, no spin

14 juli 2026 · Hans van Leeuwen

## TL;DR

- Order pipeline went dark for 2 days — someone changed a live production system, no sign-off.
- 888 of 890 shipments had zero tracking data. Nobody caught it. We found it ourselves, via one API query.
- Our own AI stack caught a failure in 62 minutes, rebuilt the missing tracking pipe, runs 24/7 — infra already paid for.
- Ask: €250–350/month to make monitoring permanent. Decision needed now, not a meeting about a meeting.

## What actually happened (root cause, not vibes)

- 1. 7–8 July** — someone pushed a German storeview to the *live* Magento environment. No sign-off, no rollback plan. Order-country detection broke, Channable → Magento import failed. **Orders stopped processing for 2 days**, during our eBay DE launch week. We found it, diagnosed it, and told the agency to fix it — not the other way around.
  - 2. 11 July** — one API query against our own Magento shows **888 / 890 shipments (99.8%)** have zero tracking data. Apparently true for a while. Nobody flagged it. Not the platform, not the agency.
  - 3. 8 July** — asked a basic order-status question. Answer: *“that’s a Magento thing, you’d need to loop in Atvise.”* We pay a platform partner and still can’t get a straight answer on our own order status without a ticket.
- Pattern: we detect, we diagnose, they patch. That’s backwards. The system should detect. We should just get told.**

## The math

|                              |                                                                                                                       |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Storeview outage, 2 days     | ~€360–700 lost revenue (run rate vs. target pace) + ~2 days of our time spent diagnosing someone else’s mistake       |
| eBay DE launch delay, 1 week | ~€4,900 deferred marketplace revenue at plan pace (€255K/12mo projection)                                             |
| 888 untracked shipments      | Marketplace seller-metric risk (unquantified but real) + hundreds to low-thousands in “where’s my order” support load |
| Atvise contract cost         | <b>Unknown to me</b> — finance/ops needs to supply this number before the next review                                 |

None of this required a new vendor. It required a **read-only monitor that already exists and already works**.

## What we already built — not a pitch, a fact sheet

Failure detection: **62 minutes** from broken order to alert (bol.com, 21 May — two orders, caught automatically). Full Magento data pulled daily via REST API — **39,853 SKUs**, zero manual work. Built the tracking-injection pipeline that made the 14 July eBay order actually deliver tracking to the customer — the piece that was supposed to already exist and didn’t. Root-caused the storeview outage in **under 24 hours**, fix ready before the next meeting. **91,558** infrastructure health checks logged since March, zero extra cost. This isn’t a plan. It’s already shipped and already working.

## THE ASK

**€250–350/month — less than we pay Channable — to keep this running permanently: order + site monitoring every 15 minutes, daily tracking/feed audits, weekly report. Read-only. No write access without explicit sign-off. 60-day kill switch if it doesn’t perform.**

**Decision: yes or no. Not “let’s discuss.”**

*Every number above traces to a source: internal API query, Gmail thread, or Supabase log — full backup in the companion evidence document. Estimates are marked as estimates; nothing here is invented.*
